

## **IN THE SPECIFICATION**

Page 7, the paragraph beginning at line 12:

As was already mentioned, the ~~data processing unit~~ standby power supply unit 30 permanently supplies the communication unit 32 of the controller 26 with an operating voltage. The communication unit 32 is preferably a network adapter for data transmission between the controller 26 and further data processing systems connected to a local area network (LAN). The network adapter 32 is connected with the LAN modem 18 of the printer 12 via a LAN connection 46. A point-to-point connection to the service notebook 14 is established via the LAN modem 18 over the telephone network 16. The network adapter 32 has a signal output 48 to which a signal is output to activate the electrical switch 28. A voltage is preferably output to activate the electrical switch 28. Alternatively, what is known as a driver circuit can be activated with the aid of the signal, via which the electrical switch 28 is then operated. The electrical switch ~~30~~ 28 can thus be activated both via the power supply unit 22 and via the network adapter 32. The signals output by the power supply unit 22 and network adapter 32 to activate the electrical switch 28 are logically linked via an OR gate.
